Conclusions Delirium is an independent marker for increased mortality among older medical inpatients during the 12 months after hospital admission. It is a particularly important prognostic marker among patients without dementia.

### **Delirium Predicts 12-Month Mortality | Dementia and ...**

The first goal of treatment for delirium is to address any underlying causes or triggers — for example, by stopping use of a particular medication, addressing metabolic imbalances or treating an infection. Treatment then focuses on creating the best environment for healing the body and calming the brain.

### **Delirium - Diagnosis and treatment - Mayo Clinic**

Delirium is a syndrome of acute brain failure that is the direct pathophysiologic consequence of an underlying medical condition or toxic exposure. According to DSM-5, it is characterized by the acute onset of deficits in attention, awareness, and cognition that fluctuate in severity over time. Delirium represents global brain dysfunction, and thus the cognitive impairments are highly variable, including disturbances in several domains, such as memory, orientation, language, visuospatial ...
